I. Probability theory

1. Random variables
2. Conditional Probability
3. Expectation and Conditional Expectation
4. Filtration
Random variable

Let $(\Omega, \mathcal{F}, P)$ be a probability space and $(E, \mathcal{E})$ be a measurable space. A measurable function $X : \Omega \to E$ is called a random variable.
The **expected value** $\mathbb{E}[X]$ of a random variable $X$ is defined as

$$\mathbb{E}[X] = \int_{\Omega} X \, dP = \int_{\Omega} X(\omega) \, P(d\omega).$$
Conditional probability

On a probability space \((\Omega, \mathcal{F}, P)\) and for \(A, B \in \mathcal{F}\) with \(P(B) > 0\) we define the conditional probability of \(A\) given \(B\) as

\[
P(A \mid B) = \frac{P(A \cap B)}{P(B)}.
\]

Let \(X\) be a random variable; then we define the conditional probability \(P(A \mid X)\) to be a random variable with

\[
P(A \mid X)(\omega) = P(A \mid X = X(\omega)).
\]
Conditional expectation

Given a random variables $X$ on a prob. space $(\Omega, \mathcal{F}, P)$ and a $H \in \mathcal{F}$, we define the **conditional expectation** $\mathbb{E}[X \mid H]$ to be

$$\mathbb{E}[X \mid H] = \int_{\Omega} X(\omega) \, P(d\omega \mid H).$$
Conditional expectation

Given a random variables $X$ on a prob. space $(\Omega, \mathcal{F}, P)$ and a sub-$\sigma$-algebra $\mathcal{H} \subseteq \mathcal{F}$ we call **conditional expectation** of $X$ given $\mathcal{H}$ as a measurable function $\mathbb{E}[X \mid \mathcal{H}]$ such that

$$\int_H \mathbb{E}[X \mid \mathcal{H}]dP = \int_H XdP, \ \forall H \in \mathcal{H}.$$ 

The **conditional expectation** of $X$ wrt another random variable $Y$ is the random variable

$$\mathbb{E}[X \mid Y = y] = \int_\Omega X(\omega) P(d\omega \mid Y = y) = \mathbb{E}[X \mid \sigma(Y)].$$
A (discrete) **stochastic process** is a sequence of random variables from a probability space \((\Omega, \mathcal{F}, P)\) to a measurable space \((E, \mathcal{E})\), that is \(\{X_k\}_{k \in \mathbb{N}}\).
Filtration

Formally, a filtration over a prob. space \((\Omega, \mathcal{F}, P)\) is a sequence of sub-\(\sigma\)-algebras of \(\mathcal{F}\), \(\{F_k\}_{k \in \mathbb{N}}\) so that

\[
\mathcal{F}_0 \subseteq \mathcal{F}_1 \subseteq \ldots \subseteq \mathcal{F}.
\]
Formally, a **filtration** over a prob. space \((\Omega, \mathcal{F}, P)\) is a sequence of sub-\(\sigma\)-algebras of \(\mathcal{F}\), \(\{F_k\}_{k \in \mathbb{N}}\) so that

\[
\mathcal{F}_0 \subseteq \mathcal{F}_1 \subseteq \ldots \subseteq \mathcal{F}.
\]

- The space \((\Omega, \mathcal{F}, \{F_k\}_k, P)\) is called a **filtered** prob. space.
Formally, a filtration over a prob. space \((\Omega, \mathcal{F}, P)\) is a sequence of sub-\(\sigma\)-algebras of \(\mathcal{F}\), \(\{F_k\}_{k \in \mathbb{N}}\) so that

\[
\mathcal{F}_0 \subseteq \mathcal{F}_1 \subseteq \ldots \subseteq \mathcal{F}.
\]

- The space \((\Omega, \mathcal{F}, \{\mathcal{F}_k\}_{k \in \mathbb{N}}, P)\) is called a filtered prob. space.
- A filtration \(\{F_k\}_{k \in \mathbb{N}}\) represents the flow of information as the experiment goes on in time,
Filtration

Formally, a filtration over a prob. space \((\Omega, \mathcal{F}, P)\) is a sequence of sub-\(\sigma\)-algebras of \(\mathcal{F}\), \(\{F_k\}_{k \in \mathbb{N}}\) so that

\[
\mathcal{F}_0 \subseteq \mathcal{F}_1 \subseteq \ldots \subseteq \mathcal{F}.
\]

▶ The space \((\Omega, \mathcal{F}, \{\mathcal{F}_k\}_{k \in \mathbb{N}}, P)\) is called a filtered prob. space.
▶ A filtration \(\{F_k\}_{k \in \mathbb{N}}\) represents the flow of information as the experiment goes on in time,
▶ \(\mathcal{F}_k\) encodes the available information up to time \(k\),
Filtration – example

Take $\Omega = [0, 1]$ and $\mathcal{F} = \sigma(\Omega)$. 

\[
\begin{array}{c}
0 \\
1
\end{array}
\]
Filtration – example

Take $\mathcal{F}_0 = \{\emptyset, [0, 1]\}$ (trivially $P(\emptyset) = 0$ and $P([0, 1]) = 1$)
Filtration – example

Take $\mathcal{F}_1 \supseteq \mathcal{F}_0$ as follows

\[ \mathcal{F}_1 = \sigma ([0, 0.5), [0.5, 1]) \]
Filtration – example

Now construct a $\mathcal{F}_2 \supseteq \mathcal{F}_1 \supseteq \mathcal{F}_0$ as follows

\[ \mathcal{F}_2 = \sigma([0, 1/6), [1/6, 1/3), [1/3, 1/2), [1/2, 1]) \]
Adapted processes

We say that a stochastic process \( \{X_k\}_{k \in \mathbb{N}} \) on a filtered probability space \((\Omega, \mathcal{F}, \{\mathcal{F}_k\}_k, P)\) is adapted to the filtration \( \{\mathcal{F}_k\}_k \) if every \( X_k \) is \( \mathcal{F}_k \)-measurable. Equivalently:

\[
\mathbb{E}[X_k \mid \mathcal{F}_k] = X_k.
\]
Given \( \{X_k\}_k \) we can construct a filtration so that the given random process is adapted to it. This is called the **natural filtration** and it is \( \mathcal{F}_k = \sigma(\bigcup \{\sigma(X_j) \}_{j \leq k}) \).
Useful properties

- **Markov’s inequality.** If $X$ is a positive, integrable random variable,
  \[ P[X \geq \alpha] \leq \frac{\mathbb{E}[X]}{\alpha}. \]

- **Chebychev’s inequality.** If $X$ a finite-variance random variable
  \[ P[|X - \mathbb{E}[X]| \geq \alpha] \leq \frac{\text{Var}[X]}{\alpha^2}. \]

- **Jensen’s inequality.** For $\varphi$ convex and $X$ integrable r.v.
  \[ \varphi(\mathbb{E}[X]) \leq \mathbb{E}[\varphi(X)]. \]
The Borel-Cantelli lemma

Let \((\Omega, \mathcal{F}, P)\) be a probability space and \(\{E_i\}_i\) a sequence of events. We denote by \(\limsup_i E_i\) the following

\[
\limsup_{i \to \infty} E_i = \bigcap_{k \geq 1} \bigcup_{j \geq k} E_j
\]

Notice that

- this a set-theoretic entity and does assume/require a topology
- it is different from the limit-superior used to define the Painleve-Kuratowski limit
- \(x \in \limsup_{i \to \infty} E_i\) iff \(x\) is in every \(\bigcup_{j \geq k} E_j\)
- \(\limsup_{i \to \infty} E_i \in \mathcal{F}\)
The Borel-Cantelli lemma

Let $(\Omega, \mathcal{F}, P)$ be a probability space and $\{E_i\}_i$ a sequence of events. If

$$\sum_{i=1}^{\infty} P[E_i] < \infty,$$

then

$$P[\limsup_i E_i] = 0.$$

Markov processes

A Markov process is a stochastic process\(^1\) so that

\[
P[w(k) = \omega | w(0), w(1), \ldots, w(k - 1)] = P[w(k) = \omega | w(k - 1)].
\]

We assume our Markov processes are:

1. finite: \(w(k)\) is finite valued \(w(k) \in \mathcal{N} = \{1, \ldots, N\}\)
2. time-homogeneous: \(P[w(k) = j | w(k - 1) = i] = p_{ij}\).

\(^1\)We call stochastic process a sequence of random variables \(w(k)\) over a probability space \((\Omega, \mathcal{F}, P)\).
The transition matrix is

\[ P = \begin{bmatrix} 0.3 & 0.7 \\ 0.4 & 0.6 \end{bmatrix} \]

with

\[ \mathcal{N} = \{1, 2\} \]
A (autonomous) Markov jump linear system is a dynamical system of the form

$$x(k + 1) = \Gamma_{\theta(k)} x(k),$$

where \(\{\theta(k)\}_k\) is a finite time-homogeneous Markov process, \(x(0) = x_0\) and \(\theta(0) = \theta_0\) follows an initial distribution with \(P[\theta(0) = \omega_i] = v_i\) for \(i = 1, \ldots, N\).
Notice that $\{x(k)\}_k$ is not a Markov process, but $\{(x(k), \theta(k))\}_k$ is.
MJLS applications

Examples

1. Power systems [Li et al. 2007; Ugrinovskii, 2005]
2. Satellite control [Meskin & Khorasani, 2009]
4. Air traffic mgmt [Zhou, 2011]
5. Solar thermal receiver [Sworder & Rogers, 1983]
6. Cell growth [Horowitz et al., 2010]
7. Samuelson’s macroeconomic model [Costa et al., 1999]
8. Printer over network with random time delays [Patrinos et al., 2011]
Assume that some or all $\Gamma_i$ are unstable. How will the system trajectories look like? Example:

$$\Gamma_1 = \begin{bmatrix} 2 & -1 \\ 0.1 & 0.1 \end{bmatrix}, \Gamma_2 = \begin{bmatrix} 0.2 & 1 \\ -0.1 & 2 \end{bmatrix},$$

and

$$P = \begin{bmatrix} 0.1 & 0.9 \\ 0.9 & 0.1 \end{bmatrix}.$$

Take $x(0) = (1, 1)'$ and $P[w(0) = 1] = 0.5$. 

Unstable + Unstable = Stable?!

Stable trajectories of a MJLS with unstable subsystems.
Assume that $\Gamma_i$ are strictly Hurwitz for all $i = 1, \ldots, N$ (all stable) – how will the MJLS Trajectories look like? Will they all converge to zero?

Example:

$$
\Gamma_1 = \begin{bmatrix}
-0.5 & 2 \\
-0.5 & 0.5 \\
\end{bmatrix}, \Gamma_2 = \begin{bmatrix}
0.5 & 0 \\
1 & 0 \\
\end{bmatrix},
$$

for which $\rho(\Gamma_1) = 0.866$ and $\rho(\Gamma_2) = 0.5$, and

$$
P = \begin{bmatrix}
0.5 & 0.5 \\
0.5 & 0.5 \\
\end{bmatrix}.
$$

Take $x(0) = (1, 1)'$ and $P[w(0) = 1] = 0.5$. 

Stable + Stable = Unstable?!

While the expected value $\mathbb{E}[||x(k)||]$ converges to 0, the covariance diverges to infinity!
Is $\mathbb{E}[x(k)] \to 0$ enough?

“Averages are funny things. Ask the statistician who drowned in a lake of average depth 3 centimetres.” ~ J. Barrow, 100 things you didn't know you didn't know.
1. We learnt what a Markov process is
2. and the class of Markov jump linear systems
3. We then listed application of Markov jump systems
4. We realised there’s a lot to learn regarding MJLS...
III. MJLS dynamics
Questions

1. How do we model the evolution of a MJLS?
2. What definition(s) of stability apply to MJLS?
3. How do we control such a system?
Some definitions

For a set $F \in \mathcal{F}$ we define its characteristic function $\chi_F : \Omega \rightarrow \{0, 1\}$ as

$$\chi_F(\omega) := \begin{cases} 1, & \text{if } \omega \in F \\ 0, & \text{otherwise} \end{cases}$$

Then, notice that

$$\mathbb{E}[x(k)] = \sum_{i=1}^{N} \mathbb{E}[x(k) \chi_{\{\theta(k) = i\}}]$$

and

$$\mathbb{E}[x(k)x(k)'] = \sum_{i=1}^{N} \mathbb{E}[x(k)x(k)' \chi_{\{\theta(k) = i\}}]$$

We are going to describe the dynamics of $\mathbb{E}[x(k)]$ and $\mathbb{E}[x(k)x(k)']$. 

Some useful Hilbert spaces

Spaces $\mathbb{R}^n$ and $\mathbb{R}^{n \times m}$ are Hilbert spaces with inner products

$$\langle x, y \rangle := x'y,$$
and $$\langle X, Y \rangle := \text{tr}(X'Y)$$

We define the Hilbert space $\mathbb{H}^{n,m}$ of $N$-tuples of $m$-by-$n$ matrices, i.e., $H = (H_1, \ldots, H_N)$ with $H_i \in \mathbb{R}^{m \times n}$ with the following inner product:

$$\langle H, V \rangle := \sum_{i=1}^{N} \langle H_i, V_i \rangle$$

On $\mathbb{H}^{n,m}$ we define the norms

$$\| H \|_1 := \sum_{i=1}^{N} \| H_i \|_2,$$
and $$\| H \|_2 := \left( \sum_{i=1}^{N} \frac{\langle V_i, V_i \rangle}{\| V_i \|_f} \right)^{\frac{1}{2}}$$
Some useful Hilbert spaces

We denote by $C^n = L^2(\omega, \mathcal{F}, \mathbb{P})$ the space of $\mathbb{R}^n$-valued random variables $y$ with inner product $\langle y, z \rangle = \mathbb{E}[y'z]$ so that $\|y\| < \infty$.

We call $\ell_2(C^n)$ the space of sequences $s = \{s(k)\}_k$ with $s(k) \in C^n$ and

$$\|s\|_{\ell_2(C^n)} := \sum_{k \in \mathbb{N}} \|s(k)\|^2_{C^n} < \infty.$$

Note that $\|s(k)\|^2_{C^n} = \langle s(k), s(k) \rangle_{C^n} = \mathbb{E}[\|s(k)\|^2]$. 

2Note that $\|s(k)\|^2_{C^n} = \langle s(k), s(k) \rangle_{C^n} = \mathbb{E}[\|s(k)\|^2]$. 

Some useful Hilbert spaces

Now let \((\Omega, \mathcal{F}, \{\mathcal{F}_k\}_{k \in \mathbb{N}}, P)\) be the aforementioned probability space with a filtration \(\{\mathcal{F}_k\}_k\). We define the space \(C^n \subseteq \ell_2(C^n)\) if for every random process \(r \in C^n\), \(r(k)\) is \(\mathcal{F}_k\)-measurable, i.e., \(r\) is adapted to the filtration \(\{\mathcal{F}_k\}_k\).
MJLS dynamics

We are now going to describe the dynamics of $\mathbb{E}[x(k)]$ and $\mathbb{E}[x(k)x(k)']$. Define

$$q_i(k) = \mathbb{E} [x(k) \chi_{\{\theta(k)=i\}}]$$

And defining $q(k) := (q_1(k), \ldots, q_N(k)) \in \mathbb{H}^{1,n}$ we have

$$\mu(k) := \mathbb{E}[x(k)] = \sum_{i=1}^{N} q_i(k).$$
MJLS dynamics

We are now going to describe the dynamics of $\mathbb{E}[x(k)]$ and $\mathbb{E}[x(k)x(k)']$. Define

$$q_i(k) = \mathbb{E} \left[ x(k) \chi \{ \theta(k) = i \} \right]$$

And defining $q(k) := (q_1(k), \ldots, q_N(k)) \in \mathbb{H}^{1,n}$ we have

$$\mu(k) := \mathbb{E}[x(k)] = \sum_{i=1}^{N} q_i(k).$$

Define also

$$Q_i(k) := \mathbb{E} \left[ x(k)x(k)' \chi \{ \theta(k) = i \} \right],$$

and let $Q(k) := (Q_1(k), \ldots, Q_N(k)) \in \mathbb{H}^{n,n}$, then

$$\Sigma(k) := \mathbb{E} \left[ x(k)x(k)' \right] = \sum_{i=1}^{N} Q_i(k).$$
MJLS dynamics

The mean and covariance dynamics are described by

\[
q_j(k + 1) = \sum_{i=1}^{N} p_{ij} \Gamma_i q_i(k)
\]

and

\[
Q_j(k + 1) = \sum_{i=1}^{N} p_{ij} \Gamma_i Q_i(k) \Gamma'_i.
\]

In what follows we will define linear operators \( B : q(k) \mapsto q(k + 1) \) and \( T : Q(k) \mapsto Q(k + 1) \).
A bound on $\| x(k) \|^2$

We can show that

$$\| x(k) \|^2 \leq n \| Q(k) \|_1,$$

where notice that the left hand side norm is the norm of $C^n$, whereas the right hand side is the 1-norm in $\mathbb{H}^{n,n}$. What happens as $Q(k) \to 0$?

$^3$In $C^n = L^2(\Omega, \mathcal{F}, \mathcal{P}, \mathbb{R}^n)$ we defined the inner product $\langle x, y \rangle = \mathbb{E}[x'y]$, so the induced squared norm is $\| x \|^2 = \langle x, x \rangle = \mathbb{E}[x'x] = \mathbb{E}[\| x \|^2]$. 
Operators $\mathcal{T}$ and $\mathcal{L} = \mathcal{T}^*$

We have $Q(k + 1) = \mathcal{T}[Q(k)]$ where $\mathcal{T} : \mathbb{H}^n \to \mathbb{H}^n$ is the linear operator
$\mathcal{T}[Q] := (\mathcal{T}_1[Q], \ldots, \mathcal{T}_N[Q])$, with

$$\mathcal{T}_j[Q] := \sum_{i=1}^{N} p_{ij} \Gamma_i Q_i \Gamma_i'.$$

The adjoint of this operator is an operator $\mathcal{L}[Q] := (\mathcal{L}_1[Q], \ldots, \mathcal{L}_N[Q])$, with

$$\mathcal{L}_i[Q] := \Gamma_i \mathcal{E}_i[Q] \Gamma_i,$$

where $\mathcal{E}_i[Q] = \sum_{i=j}^{N} p_{ij} Q_j$.\(^4\)

[^4]: Use the definition, i.e., show that $\langle \mathcal{T}[Q], S \rangle = \langle Q, \mathcal{L}[S] \rangle$ for all $Q, S \in \mathbb{H}^n$. It is left as an exercise to prove that $\mathcal{T}^* = \mathcal{L}$. 

We have $q(k + 1) = \mathcal{B}q(k)$, where $\mathcal{B} : \mathbb{R}^{Nn} \to \mathbb{R}^{Nn}$ is a linear operator and is given by

$$\mathcal{B}[q] = (P' \otimes I_n) \text{blkdiag}(\Gamma_1, \ldots, \Gamma_N) \cdot q.$$ 

If $\rho(\mathcal{B}) < 1$ then $q(k) \to 0$ and $\mu(k) \to 0$, however, this does not imply $Q(k) \to 0$ or $\Sigma(k) \to 0$.

---

$^5$Spaces $\mathbb{R}^{Nn}$ and $\mathbb{H}^{1,n}$ are homeomorphic (can be thought of as the same space).
Operator $\mathcal{T}$ as a matrix

For a matrix $A \in \mathbb{R}^{m \times n}$, $A = [A_1 \cdots A_n]$ we define

$$\text{vec}(A) := [A'_1 \cdots A'_n]' \in \mathbb{R}^{mn}.$$

For $H \in \mathbb{H}^{n,m}$ with $H = (H_1, \ldots, H_N)$, $H_i \in \mathbb{R}^{m \times n}$

$$\text{vec}(H) := [\text{vec}(H_1)' \cdots \text{vec}(H_n)']' \in \mathbb{R}^{Nmn}.$$

We are looking for a matrix $T \in \mathbb{R}^{Nn^2 \times Nn^2}$ so that

$$\text{vec}(\mathcal{T}[Q]) = T \text{vec}(Q)$$

We may verify that

$$T = (P' \otimes I_{n^2}) \text{blkdiag}(\{\Gamma'_i \otimes \Gamma_i\}_i).$$
If $\mathcal{T}$ is stable, then $\mathcal{B}$ is stable

We’ve seen that $q(k) \to 0$ does not imply $Q(k) \to 0$. However, the converse holds true: If $\mathcal{T}$ is stable, then $\mathcal{B}$ is stable too!

$$\rho(\mathcal{T}) < 1 \Rightarrow \rho(\mathcal{B}) < 1.$$
1. We described the dynamics of $\mathbb{E}[x(k)]$ and $\mathbb{E}[x(k)x(k)']$
2. We introduced the Hilbert spaces $\mathbb{H}^{n,m}$, $C^n$, $\ell_2(C^n)$ and $C^n$
3. We defined $q(k)$ and $Q(k)$ to study the dynamics of $\mathbb{E}[x(k)]$ and $\mathbb{E}[x(k)x(k)']$
4. We introduced the operators $\mathcal{B}$ and $\mathcal{T}$ using which we can study the stability properties of the dynamics of $q(k)$ and $Q(k)$. 
IV. Mean square stability
Mean square stability

The MJLS $x(k + 1) = \Gamma_{\theta(k)} x(k)$ – where $\{\theta(k)\}_{k \in \mathbb{N}}$ is a Markov process – is mean square stable (MSS) if there is a $\mu$ and a $\Sigma$ so that for any initial state $x(0) = x_0$ and initial distribution of $\theta(0)$ it is

1. $\mu(k) \to \mu$,
2. $\Sigma(k) \to \Sigma$.

In our case, $\mu = 0$ and $\Sigma = 0$ and #2 implies #1.
Why MSS?

1. It’s easy to test for
2. It implies stability of the expected state dynamics
3. It implies convergence in probability, i.e., for all $\epsilon > 0$,
   \[
   P[\|x(k)\| \geq \epsilon] \rightarrow 0,
   \]
   and further
4. It implies almost sure convergence, i.e.,
   \[
   P[\|x(k)\| \rightarrow 0] = 1.
   \]
MSS $\Rightarrow$ Convergence of $\mathbb{E} [x(k)]$

MSS $\Rightarrow$ Convergence of $\mathbb{E} [x(k)]$.

Already clear from the fact that $\rho(\mathcal{T}) < 1 \Rightarrow \rho(\mathcal{B}) < 1$. Easy way to show it by Jensen’s inequality:

$$0 \leq \mathbb{E} [\|x(k)\|] \leq \mathbb{E} [\|x(k)\|^2]^{\frac{1}{2}}.$$

**BUT:** Convergence of $\mathbb{E} [x(k)] \nRightarrow$ MSS (Exercise).
MSS \iff \mathcal{T} \text{ is stable}

If we know $\mathcal{T}$ (or $T$) we can tell whether our MJLS is stable.

If $\mathcal{T}$ is stable $\iff$ MJLS is MSS.
MSS ⇔ $T$ is stable

If we know $T$ (or $T'$) we can tell whether our MJLS is stable.

If $T$ is stable ⇔ MJLS is MSS.

Proof.
Indeed, we have $Q(k+1) = TQ(k)$ and $Q(k) = T^k Q(0)$, so

$$\Sigma(k) = \sum_{i=1}^{N} Q_i(k) = \sum_{i=0}^{N} T_i^k Q_i(0)$$

Since $T$ is stable, $T^k[Q] \to 0$, thus $\Sigma(k) \to 0$.

The converse is very easy to show.
MSS $\Leftrightarrow$ MSES

MSS systems are \textit{mean square exponentially stable}, i.e., there is a $\beta \geq 1$ and $\zeta \in (0, 1)$ so that

$$
\mathbb{E} \left[ \|x(k)\|^2 \right] \leq \beta \zeta^k \|x_0\|^2, \quad \forall k \in \mathbb{N}
$$

\textbf{Proof.}

To prove that an MSS system is also MSES we need the following result from analysis: Let $\mathcal{T}$ be a linear operator with $\rho(\mathcal{T}) < 1$. Then there are $\beta \geq 1$ and $\zeta \in (0, 1)$ so that

$$
\|\mathcal{T}^k\| \leq \beta \zeta^k,
$$

where on the LHS we may have any operator norm. The rest is left as an exercise. \qed
Unstable + Unstable = Stable?

Two unstable modes:

$$\Gamma_1 = \begin{bmatrix} 2 & -1 \\ 0.1 & 0.1 \end{bmatrix}, \Gamma_2 = \begin{bmatrix} 0.2 & 1 \\ -0.1 & 2 \end{bmatrix},$$

with $\rho(\Gamma_1) = 1.9458$ and $\rho(\Gamma_2) = 1.9426$ and

$$P = \begin{bmatrix} 0.1 & 0.9 \\ 0.9 & 0.1 \end{bmatrix}.$$ 

but $\rho(T) = \rho(T) = 0.6798 < 1.$
Two stable modes:

\[ \Gamma_1 = \begin{bmatrix} -0.5 & 2 \\ -0.5 & 0.5 \end{bmatrix}, \Gamma_2 = \begin{bmatrix} 0.5 & 0 \\ 1 & 0 \end{bmatrix}, \]

for which \( \rho(\Gamma_1) = 0.866 \) and \( \rho(\Gamma_2) = 0.5 \), and

\[ P = \begin{bmatrix} 0.5 & 0.5 \\ 0.5 & 0.5 \end{bmatrix}. \]

but \( \rho(\mathcal{T}) = \rho(T) = 1.0165 > 1 \).
A MJLS is said to be stochastically stable (SS) if for all $x(0)$ and initial distributions for $\theta(0)$ it is

$$\sum_{k=0}^{\infty} \mathbb{E} \left[ \|x(k)\|^2 \right] < \infty.$$  

This is equivalent to the random process $x = \{x(k)\}_k$ being in $C^n$.  

Stochastic stability
A MJLS is MSS iff it is SS\(^6\).

**Proof.**
Since \(E[\|x(k)\|^2]\) is a sequence of \(\ell^2\), it converges \(E[\|x(k)\|^2] \to 0\). But we have

\[
0 \leq E[\|x(k)\|^2] = E[\text{tr}(x(k)x(k)')] = \text{tr} E[(x(k)x(k)')] = \text{tr} Q(k) = \Sigma(k),
\]

so \(\Sigma(k) \to 0\) for any \(x(0)\) and \(\theta(0)\).

\(^6\)This is not true for infinite Markov jump linear systems.
An $E \in \mathbb{R}^{n \times n}$ is positive semidefinite (PSD) if $x'Ax \geq 0$, $\forall x \in \mathbb{R}^n$; we denote $A \geq 0$. $E$ is positive definite (PD) if it is PSD and $x'Ax = 0$ only when $x = 0$. Space of PSD (PD) matrices: $S_+^n$ ($S_{++}^n$).

It is $A < B$ whenever $B - A > 0$.

$\mathbb{H}_+^n$: the subset of $\mathbb{H}^n$ so that $H \in \mathbb{H}_+^n$ if $H_i \in S_+^n$ for all $i$. 
Lyapunov-like stability conditions

1. A MJLS is MSS iff for every \( S \in \mathbb{H}^{n+}, S > 0 \), there exists a unique \( V \in \mathbb{H}^{n+}, V > 0 \) such that

\[
V - \mathcal{T}(V) = S.
\]

2. A MJLS is MSS iff for some \( V \in \mathbb{H}^{n+}, V > 0 \) it is

\[
\mathcal{T}(V) < V.
\]

Notice that \( V - \mathcal{T}(V) = S \) is equivalent to \( (\text{id} - \mathcal{T})V = S \), which using von Neuman’s identity yields

\[
V = \sum_{k=0}^{\infty} \mathcal{T}^k [S].
\]
A MJLS is MSS iff for every $S \in \mathbb{H}^{n+}$, $S > 0$, there exists a unique $V \in \mathbb{H}^{n+}$, $V > 0$ such that $V - \mathcal{T}(V) = S$.

**Proof.**

Sketch: we define the following system

$$Y(k + 1) = \mathcal{L}(Y(k)); \ Y(0) \in \mathbb{H}^{n}_+.$$ 

We need to prove that this is stable using the following Lyapunov function:

$$\Phi(Y) = \langle V, Y \rangle$$

Then $\mathcal{T} = \mathcal{L}^*$ will also be stable.
The first condition can also be written as

$$V = \mathcal{L}(V) + S.$$ 

and now we have

$$V = \sum_{k=0}^{\infty} \mathcal{L}^k [S]$$
MSS conditions using $\mathcal{V}$ and $\mathcal{J}$

We have defined the operators $\mathcal{T}$ and $\mathcal{L}$ as

$$\mathcal{T}_j[Q] := \sum_{i=1}^{N} p_{ij} \Gamma_i Q_i \Gamma'_i, \quad \text{and} \quad \mathcal{L}_i[Q] := \Gamma_i \mathcal{E}_i[Q] \Gamma_i.$$

We now define the (simpler) operators $\mathcal{V}$ and $\mathcal{J}^7$ as

$$\mathcal{V}_j[Q] := \sum_{i=1}^{N} p_{ij} \Gamma_j Q_i \Gamma'_j, \quad \text{and} \quad \mathcal{J}_i[Q] := \sum_{j=1}^{N} \Gamma'_j Q_j \Gamma_j.$$

Then, the MSS conditions hold also if we replace $\mathcal{T}$ with either $\mathcal{V}$ or $\mathcal{J}$.

$^7$It is $\mathcal{V}^* = \mathcal{J}$.
These stability conditions are useful:

1. For **controller design** using linear matrix inequalities (LMIs)
2. To devise **stabilizability** and **detectability** tests
3. For MJLS with additive uncertainty
4. Similar conditions apply to **nonlinear** Markovian switching systems
Let \( \{x(k)\}_k \) be the response of a MSS MJLS – all \( x(k) \) are random variables, i.e., \( x(k)(\omega) \). Let \( \{\theta(k)\}_k \) be the corresponding sequence of random parameters. Can there be a realisation \( \{\theta^*_k\} \) so that the corresponding state trajectory

\[
x(k; x(0), \theta(0), \ldots, \theta(k - 1)) \to \infty \text{ as } k \to \infty
\]
Let $\{x(k)\}_k$ be the response of a MSS MJLS – all $x(k)$ are random variables, i.e., $x(k)(\omega)$. Let $\{\theta(k)\}_k$ be the corresponding sequence of random parameters. Can there be a realisation $\{\theta^*_k\}$ so that the corresponding state trajectory

$$x(k; x(0), \theta(0), \ldots, \theta(k - 1)) \to \infty \text{ as } k \to \infty?$$

Short answer: Yes! (But the probability of running into one is zero...)
Summary:

1. MSS is a “more meaningful” (practical) stability notion than MS
2. MSS: Both $\mu(k)$ and $\Sigma(k)$ converge
3. MSS $\Leftrightarrow \mathcal{T}$ is stable
4. MSS $\Leftrightarrow$ MSES
5. MSS $\Leftrightarrow$ SS
6. MSS $\Leftrightarrow \mathcal{T}V < V$, and $V - \mathcal{T}V = S \in \mathbb{H}^{n+}$
V. Almost sure convergence
Zero probability for non converging $x(k)$

MSS $\Rightarrow$ The probability that we find a realisation of $x(k)$ that does not converge is zero.

When is this probability zero?

If this probability is zero, do we have MSS?
Almost sure convergence

Under what conditions do we have \( x(k) \to 0 \) with probability one?

We say that \( \{x(k)\}_k \) converges **almost surely** (or with probability 1) to 0 if

\[
P\left(\lim_{k} \|x(k)\| = 0\right) = 1.
\]

For a MJLS, MSS implies almost sure convergence – the converse is not true. Almost sure convergence is weaker than MSS\(^9\).

---

\(^8\)This probability is over the space of all random processes \( \{x(k)\}_k \) which satisfy the MJLS dynamics.

\(^9\)This type of convergence is not induced by some metric and does not depend on any topology.
Almost sure convergence

MSS $\Rightarrow$ Almost sure convergence

Proof.
We have $\mathbb{E} \left[ \|x(k)\|^2 \right] \leq \beta \zeta^k \|x_0\|^2$ for all $k \in \mathbb{N}$, so $\sum_{k=0}^{\infty} \mathbb{E} \left[ \|x(k)\|^2 \right]$ is finite and the rest follows from the Borel-Cantelli\textsuperscript{10} lemma using the Chebychev-Markov inequality (Exercise). \hfill \square

\textsuperscript{10}From the Borel-Cantelli lemma we have that $z(k) \to 0$ almost surely (w.p.1) whenever $\sum_{k \in \mathbb{N}} P \left[ \|z(k)\| \geq \epsilon \right] < \infty$ for all $\epsilon > 0$. 
ASC does not imply MSS! Example with $x \in \mathbb{R}$, $N = 2$:

$$\Gamma_1 = 2.5,$$ and $$\Gamma_2 = 0.1,$$

and

$$P = \begin{bmatrix} 0.5 & 0.5 \\ 0.5 & 0.5 \end{bmatrix}$$

Then this is not MSS, but it converges almost surely.\(^\text{11}\)

Interestingly, $\rho(\mathcal{T}) = 3.13$ (not MSS), but also $\rho(\mathcal{B}) = 1.3$ (not MS)!

\(^\text{11}\)See: Fang et al. 1994.

Almost sure \Rightarrow In probability
Under what conditions $\|x(k)\| \to 0$ almost surely?
Interlude: Ergodicity

A finite Markov jump process \( \{\theta(k)\} \) is called \textbf{ergodic} if from every mode \( i \in \mathcal{N} \) we can move to any mode \( j \in \mathcal{N} \) (not necessarily in one step).

Let \( \pi_i(k) := P[\theta(k) = i] \). Under the ergodicity assumption, there is a probability distribution \( \pi = \{\pi_1, \ldots, \pi_N\} \), \( \pi_i > 0 \), such that

\[
\pi_i(k) \to \pi_i.
\]

And we can compute \( \pi \) solving\(^{12}\)

\[
P'\pi = \pi.
\]

\(^{12}\)For details, I recommend the lecture notes of J. Gravner (UC Davis) on “introductory probability”.
Take $\nu$ pos. integer and let

$$\tilde{\theta}(k) = (\theta(k\nu + \nu - 1), \ldots, \theta(k\nu)) \in \mathcal{N}^\nu$$

be a Markov chain. Take $\iota = (i_{\nu - 1}, \ldots, i_0)$ and $\tau = (j_{\nu - 1}, \ldots, j_0) \in \mathcal{N}^\nu$. The transition probabilities of $\tilde{\theta}(k)$ are

$$P\left[\tilde{\theta}(k + 1) = \tau \mid \tilde{\theta}(k) = \iota\right] = p_{i_{\nu - 1}j_0}p_{j_0j_1} \cdots p_{j_{\nu - 1}j_{\nu - 1}}.$$ 

We have $P\left[\tilde{\theta}(k) = \tau\right] = P\left[\theta(k\nu) = j_0\right] p_{j_0j_1} \cdots p_{j_{\nu - 1}j_{\nu - 1}}$ and as $k \to \infty$ this converges to

$$\tilde{\pi} := \pi_{j_0}p_{j_0j_1} \cdots p_{j_{\nu - 1}j_{\nu - 1}}.$$
Conditions for ASC

**Theorem**

Let \( \tilde{\Gamma}_i \coloneqq \Gamma_{i_{\nu - 1}} \cdots \Gamma_{i_0} \). If there is \( \nu \) \( \text{pos. integer.} \), s.t.

\[
\prod_{i \in \mathcal{N}^\nu} \|\tilde{\Gamma}_i\|^{\tilde{\pi}_i} < 1,
\]

then \( x(k) \to 0 \text{ a.s.;} \quad \| \cdot \| \text{ can be any matrix norm.} \)
Exercises

Exercise 1. Determine a system with \( n = 2, \ N = 2 \) which is ASC but not MSS.

Exercise 2. Show that a system with \( n = 1, \ N = 2, \) and \( \theta(k) \): i.i.d. with \( \pi_1 = \pi_2 = 0.5 \) and \( \Gamma_1 = \alpha, \Gamma_2 = \beta \) is ASC if and only if \(|\alpha\beta| < 1|\). 

Exercise 3. For a stochastic process \( \{x(k)\}_k \) we know that \( \mathbb{E}[x(k)] \to 0 \). Is the process ASC?
Summary:

1. Almost sure convergence is weaker than MSS
2. ASC is convergence w.p.1.
3. ASC implies convergence in probability
4. The notion of almost sure convergence is not induced by a topology
5. A system can be ASC but not MSS or even MS
6. When the Markov process is ergodic, $\pi_i(k)$ converges
VI. Feedback stabilisation
Feedback stabilisation

We need to design a mean square stabilising controller for the system

\[ x(k+1) = A_{\theta(k)}x(k) + B_{\theta(k)}u(k). \]

We assume \( x(k), \theta(k) \) are measured and the controller has the form

\[ u(k) = \kappa(\theta(k), x(k)) = F_{\theta(k)}x(k), \]

so the closed-loop MJLS is

\[ x(k+1) = (A_{\theta(k)} + B_{\theta(k)}F_{\theta(k)})x(k). \]
Feedback stabilisation

The closed-loop system is MSS if there is $V \in \mathbb{H}_+^n$ so that $\mathcal{T}(V) < V$, i.e., for all $j \in \mathcal{N}$

$$V_j - \sum_{i=1}^{N} p_{ij} (A_{\theta(k)} + B_{\theta(k)} F_{\theta(k)}) V_i (A_{\theta(k)} + B_{\theta(k)} F_{\theta(k)})' > 0$$

which can be written as a LMI using the Schur complement lemma (Exercise).
Feedback stabilisation

Comments:

1. We have one controller for each mode.
2. For each $i \in \mathcal{N}$, we didn’t select $F_i$ so as to stabilise $(A_i, B_i)$.
3. Had we done that, would the closed-loop MJLS be MSS?
4. In practice, $\theta(k)$ may not be known exactly.
Assume $\theta(k)$ is not available at time $k$, but we have an estimate $\hat{\theta}(k) \in \mathcal{N}$ (which defines a random process). Then,

$$u(k) = F_{\hat{\theta}(k)} x(k),$$

and the closed-loop MJLS will be

$$x(k + 1) = (A_{\theta(k)} + B_{\theta(k)} F_{\hat{\theta}(k)}) x(k).$$
Stabilisation with inexact knowledge of $\theta(k)$

We define the following filtration $\{M_k\}_{k \in \mathbb{N}}$ with $M_0 = \mathcal{F}_0$ and $M_k$ is the $\sigma$-algebra generated by

$$\{x(0), \theta(0), x(1), \theta(1), \hat{\theta}(0), \ldots, x(k), \theta(k), \hat{\theta}(k - 1)\}.$$ 

We assume that

$$P\left[\hat{\theta}(k) = s \mid M_k\right] = P\left[\hat{\theta}(k) = s \mid \theta(k)\right] =: \rho_{\theta(k)s}.$$ 

This means that

$$\rho_{is} = \{\text{probability that } \theta(k) = i \text{ while we estimated } \hat{\theta}(k) = s\}$$

and

$$\rho_{is} = \{\text{probability of success: } \theta(k) = \hat{\theta}(k) = i\}$$
Stabilisation with inexact knowledge of $\theta(k)$

Let

$$p = \min_i \rho_{ii}.$$  

Let $\mathcal{T} : \mathbb{H}^n \to \mathbb{H}^n$ be defined as before with $\Gamma_i = A_i + B_i F_i$. Since $\mathcal{T}$ is stable, there are $\beta \geq 1$ and $\zeta \in (0, 1)$ s.t.$^{13}$

$$\|\mathcal{T}^k\|_1 \leq \beta \zeta^k.$$  

Finally, let

$$c_0 := \max \left\{ \|A_i + B_i F_s\|^2, i, s \in \mathbb{N}, i \neq s, \rho_{is} > 0 \right\}.$$  

$^{13}$Question: How do we determine those parameters? Can you give an example when $N = 1$ and $N = 2$?
Stabilisation with inexact knowledge of $\theta(k)$

MSS condition:

\[ p > 1 - \frac{1 - \zeta}{c_0 \beta}. \]

**Proof.**
The proof is a bit lengthy and can be found in the book of Costa et al. (Lemma 3.44). Sketch: We show that

\[ 0 \leq Q_j(k + 1) \leq T_j[Q(k)] + S_j[Q(k)], \]

where $S : \mathbb{H}^n \to \mathbb{H}^n$ is such that $\|S\|_1 \leq c_0(1 - p)$. \qed
